

the RBAC or ABAC FAQ is missed

the use cases I ahve already given as input, i also talked about the insight on productivity and other things which are not mentioned here at all

Here's a **comprehensive FAQ and use case summary** integrating all your points—including RBAC/ABAC, productivity insights, and the external integration scenario.

Expanded FAQs

1. What is RBAC/ABAC and how is it implemented in AAM?

- **RBAC (Role-Based Access Control):** Manifests specify every action's allowed roles (e.g., AUDIT_MANAGER, FRAUD_ANALYST), enabling fine-grained, team/org-wide permissioning.
- **ABAC (Attribute-Based Access Control):** Each workflow can enforce row-level, attribute-derived rules based on context (dept, site, business unit, risk_category, etc.), supporting even more granular restrictions.
- These controls are not duplicated per use case: they're managed in central Security policies where each action_id gets its own RBAC/ABAC block.
- If a use case requires fundamentally different governance, security, or compliance, a new action_id with distinct RBAC/ABAC rules is created (e.g., international audits having stricter entitlements).

2. How does the agentic platform generate operational/productivity insights?

- Every event (button click, API call, action execution, approval, etc.) is logged with full timestamps and user-context.
- This event data serves as **training/analytics data** for productivity analysis: measuring analyst time-to-resolution, workflow bottlenecks, manual vs. automated effort, and user adoption.
- Management can use dashboards to track who is most/least productive, which processes are most/least efficient, and where to deploy further automation for ROI improvements.

3. How do external applications and integrations (JIRA, PTS, Marketplace, etc.) work with Agentic AI?

- Agentic AAM supports mapping and automation of workflows targeting external applications.
- SMEs can use a training UI or configuration flow to define how a set of API calls (across JIRA, Marketplace, PTS, etc.) can be clubbed into atomic agentic tasks, regardless of

whether those platforms are internally managed.

- The manifest lists allowed external domains, supported integrations, and security rules for external data handling.

4. What is the difference between enabling/disabling actions versus entire agentic automation?

- Any granular workflow/action can be instantly disabled for agentic execution via an enable flag (`enabled: false`). Humans can still execute natively unless blocked at the system level.
- The root manifest (`AAM_Root.yaml`) provides a switch to disable all automation platform-wide (e.g., in case of catastrophic failure, regulatory enforce, or DDoS).

5. How can I disable all use cases for a certain workflow/action family?

- Parent/child hierarchy for actions lets SMEs bulk-disable (e.g., all “approve audit” flows) by parent action, category, or tag in a single edit.

6. Can the platform differentiate truly distinct workflows from mere variations?

- Yes. Fully distinct use cases/flows get their own `action_ids` and security rules (e.g., local vs. international approval).
- Variations (such as standard vs. expedite approval) are grouped under use case/`action_id`, sharing governance and security.

7. How do I control concurrency and performance at scale?

- The root manifest includes controls for the max allowed concurrent users and flows, plus system load/fallback settings and emergency notification props.

Use Cases Discussed

- **Audit Approval (Approve Audit)**

Multiple UCs for local, international, exception, and expedite flows, each agentially orchestrated with RBAC/ABAC, enable/disabling possible at parent and child levels.

- **Risk Escalation**

Threshold and manual escalation workflows for risk events, supporting compliance, supervisor approval, analytics, and agentic enable/disable.

- **Fraud Detection**

ML-detected, analyst-flagged, and customer-reported fraud workflows with role/attribute-controlled permissions, AI escalation, and productivity/event logging.

- **External System Integration (JIRA/PTS/Marketplace)**

SMEs and admins can configure agentic workflows spanning multiple external APIs, documenting clubbed multi-system automation directly in the manifest for compliance, auditing, and further training.

- **Operational and Productivity Insights**

All user/system events generate actionable training and analytics data that serve both business reporting and model improvement. Dashboards can show analyst time-to-

resolution, productivity, slow processes, adoption rate, and efficiency improvements from automation.
